#### Abstract

An efficient total synthesis of (-)-hyrtiosal was accomplished in linear 10 steps from commercially available (-)-sclareol. An acid-catalyzed cyclization of $\alpha, \beta$-unsaturated amide successfully constructed the key intermediate Weinreb amide 4 b with bulky $N, O$-dimethylhydroxylamine group, which benefited the stereoselectivity in the epoxidation of 5 . One-pot reaction involved the rearrangement of epoxide 5 and the thiol protection of aldehyde 6 catalyzed by $\mathrm{BF}_{3} \cdot \mathrm{Et}_{2} \mathrm{O}$ was developed to give a $74 \%$ yield. This practical synthetic route provided (-)-hyrtiosal on grams scale. © 2012 Trade Science Inc. - INDIA

## INTRODUCTION

(-)-Hyrtiosal 1, embodying the unique structure of hyrtiosane skeleton, was firstly isolated from the Okinawan Marine sponge Hyrios erectus by Iguchi et. al. in $1992^{[1]}$. It also existed in extracts of various sponges ${ }^{[2]}$. The stereochemistry of (-)-hyrtiosal was verified by X-ray crystallography ${ }^{[2 d]}$ and its absolute configuration was confirmed by the sample provided from total synthesis ${ }^{[3 a]}$.

Preliminary pharmacological studies demonstrated that (-)-hyrtiosal had significant cytotoxic activities against KB, Hela and PC12 cell lines ${ }^{[1,2 f]}$. Recently, (-)-hyrtiosal was reported to be a competitive inhibitor of PTP1B $\left(\mathrm{IC}_{50}=42 \mu \mathrm{M}\right){ }^{[4]}$ and HIV-1 intergrase $\left(\mathrm{IC}_{50}\right.$ $=9.6 \mu \mathrm{M})^{[5]}$.

The first total synthesis of (-)-hyrtiosal reported 9 steps ${ }^{[3]}$ from methyl isoanticopalate, which was synthesized from (-)-sclareol in 8 steps ${ }^{[6]}$. Lunardi group also succeeded in synthesizing $(-) /(+)$-hyrtiosal and their C -

16 epimers starting from copalic acid, however, with low $e e$ value ${ }^{[7]}$.

In current research, we developed a concise route to synthesize (-)-hyrtiosal in linear 10 steps from (-)-sclareol. As a key intermediate, compound 4b was synthesized from (-)-sclareol in 4 steps which could be applied in the synthesis of various marine natural diterpene products with a broad spectrum of bioactivity.

Weinreb amide 4 b acted as the key intermediate had several other reasons as well. The introduction of $N, O$-dimethylhydroxylamine group could improve the stereoselectivity of 5 in epoxidation as well as the Weinreb amide could be directly reduced to the corresponding aldehyde with lithium aluminum hydride (LAH) or diisobutylaluminum hydride (DIBAL-H). Compared with the classic method, this new developed synthetic route has the benefits of shorter reaction sequence as well as the better overall yields.

## EXPERIMENTALSECTION

## General information

Commercially available reagents were used without further purification unless otherwise noted. All the reactions were carried out in oven-dried glass flasks under $\mathrm{N}_{2}$ atmosphere at room temperature unless otherwise noted. The following solvents were distilled before used: tetrahydrofuran (THF) was distilled from Na , dichloromethane and toluene were distilled from $\mathrm{CaH}_{2}$. The reaction monitoring was accomplished by TLC on silica gel polygram SILG/UV 254 plates. All yields refer to isolated products. NMR spectra were recorded for ${ }^{1} \mathrm{H}$ NMR at 400 MHz and ${ }^{13} \mathrm{C}$ NMR at 100 MHz using TMS as internal standard on a Bruker AVANCE 400 MHz spectrometer.

The solution of diethyl ( $N$-methoxy- $N$ -methylcarbamoyl-methyl) phosphonate ( $67.1 \mathrm{~g}, 286$ $\mathrm{mmol})$ in THF ( 150 mL ) was added dropwise to the solution of $\mathrm{NaH}(12.6 \mathrm{~g}, 60 \%$ in mineral oil, 315 mmol ) in THF ( 300 mL ) at $0^{\circ} \mathrm{C}$. After it was warmed to room temperature and stirred for 1 h , the reaction was cooled to $0^{\circ} \mathrm{C}$ again and $2(29.5 \mathrm{~g}, 113 \mathrm{mmol})$ in THF ( 100 mL ) was added dropwise. The reaction was quenched with water $(100 \mathrm{~mL})$ after the starting material was consumed. Then, THF was removed under reduced pressure and the residue was extracted with EtOAc (3 $\times 100 \mathrm{~mL}$ ). The organic layer was washed with brine, dried over MgSO 4 , filtered and concentrated under reduced pressure. ## RESULTS/DISCUSSION

Using the reported process, 4a was synthesized first. However, all tentative efforts failed to directly transform 4 a to amide $4 b$ with known procedures ${ }^{[8]}$. Therefore, a modified strategy was applied to obtain 4 b starting from 2. The Emmon-Horner Wittig reaction of 2 with diethyl ( N -methoxy- N - methylcarbamoylmethy 1) phosphonate ${ }^{[10]}$. using sodium hydride as base offered the expected $\alpha, \beta$-unsaturated amide 3 in excellent yield. Because of the high stereoselectivity of $3(\mathrm{E} /$ $\mathrm{Z}=15: 1$ ) the cyclization in anhydrous formic acid lead to 4 b (mp. 111.0-113.0 C) as a single conformation with moderate yield. The configuration of 4 b was further confirmed by the X-ray crystallographic analysis ${ }^{[11]}$. (Scheme 1, Figure 1)

Figure 2 : X-ray structure of compound 6.

After 4 b was obtained, the synthesis of aldehydes 8 and 9 were performed as shown in Scheme 2. Owing to the existence of the bulky $N, O$-dimethyl hydroxylamine group, epoxidation of Weinreb amide 4 b only occurred from the less-hindered endo face to furnish the sole compound 5 as a waxy solid. The next rearrangement of epoxide 5 , catalyzed by $\mathrm{BF}_{3} \cdot \mathrm{Et}_{2} \mathrm{O}$, successfully provided compound 6 and its configuration of C-13 was determined by X-ray study (Figure 2) ${ }^{[11]}$. As the thiol protection could also be promoted by $\mathrm{BF}_{3} \cdot \mathrm{Et}_{2} \mathrm{O}$, one-pot method was developed to directly gain compound 7 from 5 in $74 \%$ yield as an oil. The redection of amide 7 with LAH directly gave aldehyde 8 with $68 \%$ isolated yield. The aldehyde 8 was then treated with (methoxymethyl)-triphenylphosphonium chloride using LiHMDS as base to give the corresponding enol ether, which could be transformed to aldehyde 9 in the presence of catalytic amount of $p$-toluenesulfonic acid (Scheme 2).

With aldehyde 9 in hand, Urones' procedure was used to gain (-)-hyrtiosal in $26 \%$ yield as a white solid and its $\mathrm{C}-16$ epimer in $31 \%$ yield as white solid (sepa-

## CONCLUSION

In summary, a practical total synthesis of (-)hyrtiosal involving the construction of amide 4 b , which has the advantages of improving the stereoselectivity in epoxidation and reducing the reaction steps, together with the Lewis-acid mediated rearrangement of epoxide 5 as key steps has been achieved over 10 steps from commercially available (-)-sclareol. This synthetic strategy can provide gram scale of (-)-hyrtiosal which can be used in the biological studies.
