ABSTRACT
Thin films of LiCoO$_2$ were prepared by pulsed laser deposition technique. Two important deposition parameters such as substrate temperature and oxygen partial pressure during the thin film deposition were controlled. Electrochemical measurements were carried out on Li//LiCoO$_2$ cells with a lithium metal foil as anode and a LiCoO$_2$ film as cathode of 1.5 cm$^2$ active area. Cyclic voltammetry (CV) measurements have been carried out at sweep rate $\alpha = 1$ mV/s. The Li//LiCoO$_2$ cells were tested in the potential range 2.6 – 4.2 V. Specific capacity as high as 205 mC/cm$^2$ was measured for the film grown at 700 $^\circ$C. © 2009 Trade Science Inc. - INDIA

INTRODUCTION
Lithiated transition metal oxides such as LiMO$_2$ (Where M = Co, Ni, Mn etc.) have received considerable attention in recent years as high voltage positive electrode materials for use in secondary lithium batteries$^{[1]}$. Among these, the high cycling stability and high cell potential against lithium makes LiCoO$_2$ an attractive cathode material in the fabrication of all solid state rechargeable microbatteries$^{[2,3]}$. Its theoretical specific capacity and energy densities are 274 mAh/g and 1070 Wh/kg respectively. Experimentally it has been observed that the material delivers only capacity around 140 mAh/g due to structural considerations.

The layered LiCoO$_2$ consists of a close packed network of oxygen ions with Li and Co ions on alternative (111) planes of the cubic rocksalt sub-lattice. The edges of CoO$_6$ octahedral were shared to form CoO$_2$ sheets and lithium ions can move in two-dimensional directions between CoO$_2$ sheets. Thus the layered LiCoO$_2$ has an anisotropic structure and thereby electrochemical lithium insertion / extraction behaviour must depend strongly on the orientation of the microcrystallites. The growth of LiCoO$_2$ thin films with preferred orientation is known to be crucial. Several thin film deposition techniques such as RF sputtering$^{[2,4]}$, pulsed laser deposition$^{[4-8]}$, electrostatic spray deposition$^{[9]}$ and chemical vapour deposition$^{[10]}$ were employed for the growth of LiCoO$_2$ thin films. A brief literature survey reveals that it is difficult to grow stoichiometric and stable c - axis oriented LiCoO$_2$ thin films by several physical vapour deposition methods due to many growth kinetic processes which occur in vacuum or at low oxygen partial pressures.

Pulsed laser deposition (PLD) has been widely recognized as a very promising, versatile and efficient method for the deposition of metal oxide thin films$^{[11]}$. When PLD is carried out in the atmosphere of a chemi-
Electrochemical properties of pulsed laser deposi-
tion (RPLD), the flux of the laser ablated material interacts with the gas molecules all along the transit from the target to the collector surface. The resulting deposited layer was found to have a chemical composition substantially the same as the base or starting material. Preliminary investigations on pulsed laser deposited LiCoO$_2$ thin films were carried out by Julien et al.$^5$. Iriyama et al.$^6$ and studied the electrochemical performance. They observed that the reactivity in single-phase region at potentials more positive than 4.0 V was lower than that of randomly oriented films. Poly-crystalline layered R$_3$$_\text{m}$ phase thin films of LiCoO$_2$ were grown by PLD using Nd:YAG laser by Julien et al.$^{12}$. This LiCoO$_2$ cathode active films were found to deliver a specific capacity of 195 mC/cm$^2$ um in the voltage range 2.0 - 4.2 V. In the present study the influence of deposition parameters on the electrochemical properties of pulsed laser deposited LiCoO$_2$ thin films were reported.

**EXPERIMENTAL**

LiCoO$_2$ films were grown by pulsed laser deposition technique on silicon substrates maintained at temperatures in the range 200 - 700 °C. LiCoO$_2$ target was prepared by sintering a mixture of high purity LiCoO$_2$ and Li$_2$O powders (Cerac products) with excess of Li i.e. Li/Co > 1.0 by adding Li$_2$O. The mixture was crushed and pressed at 5 tons/cm$^2$ to make tablets of 3 mm thick and 13 mm diameter. To get quite robust targets, the tablets were sintered in air at 800 °C. The typical substrates i.e. Si wafers were cleaned using HF solution. The target was rotated at 10 rotations per minute with an electric motor to avoid depletion of material at any given spot. The laser used in these experiments is the 248 nm line of a KrF excimer laser (Luminics PM 882) with 10 ns pulse with a repetition rate of 10 Hz. The rectangular spot size of the laser pulse was 1x3 mm and the energy 300 mJ. The target substrate distance was 4 cm. The deposition temperature was maintained with thermocouple and temperature controller. During the deposition pure oxygen was introduced into the deposition chamber and desired pressure was maintained with a flow controller.

The electrochemical measurements were carried out on Li/LiCoO$_2$ cells with a lithium metal foil as anode and LiCoO$_2$ film as cathode of 1.5 cm$^2$ active area using a Teflon home-made cell hardware. The silicon substrate was mounted on Ag wire with silver paint and covered by insulating epoxy leaving only the PLD film as active area. The electrolyte consisted of 1 M LiClO$_4$ dissolved in propylene carbonate. Electrochemical titration was made by charging and discharging the cells using the galvanostatic mode of a Mac-Pile single 608 electrochemical analyzer system in the potential range between 2.0 and 4.2 V. Quasi open circuit voltage profiles were recorded using current pulses of 5 μA cm$^{-2}$ supplied for 1 h followed by a relaxation period of 0.5 h. Electrochemical potential spectroscopy (ECPS) was performed using 5 mV potential steps.

**RESULTS AND DISCUSSION**

Pulsed laser deposited LiCoO$_2$ films are pin-hole free as revealed from optical microscopy and well adherent to the substrate surface. The thickness of LiCoO$_2$ films is 250 nm. The influence of oxygen partial pressure (P(O$_2$)) and deposition temperature (Ts) on the electrochemical properties of the films are systematically studied. The chemical compositional studies made on LiCoO$_2$ films revealed that a minimum of 100 mTorr oxygen partial pressure is required to grow nearly stoichiometric films.

The electrochemical measurements were carried out on Li/LiCoO$_2$ cells with a lithium metal foil as anode and LiCoO$_2$ film as cathode of 1.5 cm$^2$ active area using a Teflon home-made cell hardware. The silicon substrate was mounted on Ag wire with silver paint and covered by insulating epoxy leaving only the PLD film as active area. The electrolyte consisted of 1 M LiClO$_4$ dissolved in propylene carbonate. Figure 1 shows the cyclic voltammogram for a Li/LiCoO$_2$ with a film grown at temperature 700 °C in an oxygen partial pressure of 100 mTorr. There are two sets of well defined current peaks observed in the CV diagram corresponding to the oxidation and reduction reaction: they are located at 3.73 and 3.63 V for the LiCoO$_2$ film. These CV features are associated with the redox process of Co$^{3+}$ to Co$^{4+}$ and vice-versa, when
lithium is extracted from, and inserted into the Li$_2$CoO$_3$ phase. The redox couple with a mid-peak potential of about 3.68 V is considered to be a single-phase insertion/deinsertion reaction of lithium ions in LiCoO$_2$. Figure 2 shows the cyclic voltammogram for a Li//LiCoO$_2$ cell with a film grown at temperature 300 °C in an oxygen partial pressure of 100 mTorr. The peaks are slightly shifted to lower potential due to the small grain size for the films grown at lower substrate temperature.

The incremental capacity curve (-δx/δV) versus cell voltage for the Li//LiCoO$_2$ thin film cell that is derived from the charge curve (Figure 3) exhibits only one well defined voltage, which displays a peak at 3.64 V. The electrochemical process seems to be a classical intercalation mechanism for the lithium ions into the Li$_2$CoO$_3$ matrix as indicated by the peak. These results suggest that about 0.5 Li can be removed at charge potential up to 4.2 V. The PLD LiCoO$_2$ film grown at substrate temperature 700 °C has interesting electrochemical properties for the microbattery application. In the high voltage region, such a cell delivers a specific capacity of 205 mC/cm$^2$μm$^{12}$, which is slightly decreased for the films grown at 300 °C and the cell delivered a higher specific capac-

The incremental capacity curve (-δx/δV) versus cell voltage for the Li//LiCoO$_2$ thin film cell that is derived from the charge curve (Figure 3) exhibits only one well defined voltage, which displays a peak centered at 3.64 V. The electrochemical process seems to be a classical intercalation mechanism for the lithium ions into the Li$_2$CoO$_3$ matrix as indicated by the peak. These results suggest that about 0.5 Li can be removed at charge potential up to 4.2 V. The PLD LiCoO$_2$ film grown at substrate temperature 700 °C has interesting electrochemical properties for the microbattery application. In the high voltage region, such a cell delivers a specific capacity of 205 mC/cm$^2$μm$^{12}$. The potentials are slightly decreased for the films grown at 300 °C and the cell delivered a higher specific capac-

Typical charge discharge curves of Li//LiCoO$_2$ cells using pulsed laser deposited film grown at substrate temperature 700 °C in an oxygen partial pressure of 100 mTorr are shown in Figure 3. Electrochemical measurements were carried out at a rate of C/100 in the potential range 2.0 - 4.2 V; as such, the voltage profile should provide a close approximation to the open circuit voltage (OCV). From the electrochemical features, we may make some general remarks that are (1) an initial voltage about 2.15 V versus Li/Li$^+$ was measured for LiCoO$_2$ thin film cathode cells, which is lower to that recorded in the galvanic cell using crystalline cathode$^{13}$, (2) the cell voltage profiles display the typical profile currently observed for Li$_x$CoO$_2$ cathodes, (3) the cell voltage is a function of the structural arrangement in the film and thus depends on the substrate deposition temperature. These potentials slightly increased for films grown at high substrate temperature.

Electrochemical properties of pulsed laser deposited LiCoO$_2$ films

CONCLUSIONS

Thin films of LiCoO$_2$ were prepared by pulsed laser deposition. PLD films were found to be uniform with regard to the surface topography, thicknesses and well adherent to the substrate surface. Cyclic voltammetry (CV) measurements have been carried out at sweep rate $\alpha = 1$ mVs$^{-1}$. The Li//LiCoO$_2$ cells were tested in the potential range 2.6 – 4.2 V. Specific capacity as high as 205 mC/cm$^2$ $\mu$m was measured for the film grown at 700 °C. This performance is due to the good crystallinity of the LiCoO$_2$ films grown by PLD technique. These results suggest that the open and porous structured LiCoO$_2$ PLD films find potential applications as binder free electrode in the fabrication of all solid state microbatteries.
