ABSTRACT

This study aimed to examine the relationship between the gene polymorphism of MMP-1 and the prognosis of hepatitis C virus (HCV)-related hepatocellular carcinoma (HCC) in Egyptian population. Methods: The study enrolled 180 Egyptian individuals classified into 3 groups: Group I: consists of 60 apparently healthy individuals served as control; Group II: consists of 60 individuals diagnosed with HCV; Group III: consists of 60 individuals diagnosed with HCC. Gene polymorphism of MMP-1 -16071G/2G using restriction fragment length polymorphism (RFLP) for amplified genomic DNA was analyzed. Results: In HCC prognosis, MMP-12G carriers had higher probability of developing HCC when compared to healthy individuals. Conclusion: MMP-1 2G allele may be a cooperative risk factor for poor prognosis in HCC patients, suggesting that further studies with larger sample size should be investigated to ensure that this gene polymorphism might be a potential marker for predicting the prognosis of HCC patients in Egyptian patients. © 2014 Trade Science Inc. - INDIA

INTRODUCTION

Hepatocellular carcinoma (HCC) is ranked to be the most common cancer in many countries. Recently, HCC was reported to be the fifth most common cancer in males, the eighth common cancer in females and about 560 000 cases are discovered per year, more than 80% of which occur in the developing countries[1]. Egypt is known for being the country in the world where the rate of HCV is higher, about 24% of the people are estimated to carry HCV and the more than 50% of blood donors have anti-HCV in some towns. Chronic infection with hepatitis C virus (HCV) is considered one of the major causes of end-stage liver disease including cirrhosis and hepatocellular carcinoma[2,3].

Recent studies have highlighted the role of the ECM and shown the importance of deregulated ECM dynamics in molecular etiology of cancer development[4]. Degradation of extracellular matrix is required for tumor cell migration and dissemination, a process that is facilitated by a family of neutral proteolytic enzymes known as the matrix metalloproteinases (MMPs)[5].
Matrix metalloproteinases (MMPs) are a family of proteolytic enzymes that are capable of degrading various components of the extracellular matrix. They are involved in all stages of cancer progression, not only in the process of tumour invasion and metastasis, but also in as proliferation, adhesion, migration, differentiation, angiogenesis and apoptosis\(^6\). The human MMP family currently consists of 28 members of homologous zinc-dependent endopeptidases, secreted as pro-enzymes and activated after the removal of their N-terminal domain\(^7,8\). Matrix metalloproteinases (MMPs) are implicated in cancer development and progression and are associated with prognosis. Single-nucleotide polymorphisms (SNPs) of MMPs, most frequently located in the promoter region of the genes, have been shown to influence cancer susceptibility and/or progression\(^9\).

The interstitial collagenase-1 (MMP-1) is one of the principal proteinases that possesses proteolytic activity against interstitial collagens, the most abundant classes of ECM proteins in fibrotic livers\(^10\). The gene is part of a cluster of MMP genes which localize to chromosome 11q22.3 with 11 exons and 10 introns\(^11\). MMP-1 promoter gene polymorphism is the insertion/deletion of a guanine (G) at position -1,607, and has two alleles, one with a single guanine (1G) and the other with two (2G)\(^12\). The insertion of a second G nucleotide at position -1607 of MMP1 (-1607insG, rs1799750) generates a new 5'-GGGA'3 sequence that corresponds to a recognition sequence for members of Ets family of transcriptional factors\(^13\). Many studies have proved that cells containing 2G polymorphism (1G/2G or 2G/2G), which created Ets binding sites, were found to be more transcriptionally active than cells with 1G/1G genotype\(^14\).

This study examined the association of MMP-1 gene polymorphisms with the prognosis of hepatitis virus C (HCV)-related HCC patients.

**SUBJECTS & METHODS**

**Site of the study**

The study was carried out in Biochemistry and Internal Medicine Departments - Faculty of medicine, Zagazig university.

**Subjects**

The present study was carried out on 180 Egyptian individuals (71 females and 109 males) with age ranged from (39 to 61 years). They were divided into the following groups: Group I: consists of 60 apparently healthy individuals served as control (39 males and 21 females) with ages ranged from 39 to 61 with a mean value ± SD of (50.32 ± 6.84) Group II: consists of 60 individuals diagnosed with HCV (36 males and 24 females) with ages ranged from 43 to 61 with a mean value ± SD of (50.5 ± 5.45) Group III: consists of 60 individuals diagnosed with HCC (34 males and 26 females) with ages ranged from 44 to 59 with a mean value ± SD of (52 ± 4.48).

**Inclusion criteria**

All participants (except control) should be positive for serum HCV RNA.

**Exclusion criteria**

Patients who had chronic hepatitis B virus infection, alcoholism, primary biliary cirrhosis, or autoimmune liver disease will be excluded.

All individuals were subjected to the following:-

1. Measurement of AFP level by the third generation ELISA using kits from the Equipar (Saronno, Italy).
2. Measurement of liver enzymes (ALT and AST) by Bayer Opera Chemistry System (Diagnostic Division Tarrytown, NY USA).
3. Determination of MMP-1 gene polymorphism by PCR amplification followed by restriction Fragment length polymorphism (RFLP) and gel electrophoresis.

**DNA extraction**

Genomic DNA was isolated from 3 ml venous blood sample withdrawn on EDTA using genomic DNA purification kit (Fermentas) according to the manufacturer’s instructions.

**Genotype analysis**

Gene polymorphisms were detected through PCR amplification followed by digestion using restriction endonuclease enzymes for RFLP analysis. MMP1 gene 1G/2G polymorphism was genotyped using the forward primer (5'- TCGTGAGATGTCTTCCATT-3'); and the reverse primer (5'- TCTTGGATTGATTGAGAATGTAATCCAT-3'), according to previous reports\(^15\).
PCR reaction for both polymorphisms

PCR reaction was performed in a final volume of 50 µl that contained: 2X PCR Mix: 25 µl, Primer mix (2.5 µM or 1/40 of dilution 100 µM stock): 1 µl for each primer, Genomic DNA: 5 µl and Deionized water: 18 µl. The amplification was carried out using DNA thermal cycler 480, PERKIN ELMER (Norwalk, CT 06856, USA), Serial No. P 16462.

PCR conditions for MMP 1 polymorphism were; 1 min cycle for initial denaturation at 95 ºC; 35 cycles at 95 ºC for 1 min for denaturation, 55 ºC for 30 sec for annealing and 72 ºC for 30 sec for extension, followed by 1 cycle at 72 ºC for 5 minutes for final extension.[15]

Restriction enzyme digestion

The PCR products were digested with restriction endonucleases (Fast Digest, Thermo Scientific) and subjected to electrophoresis on a 2% agarose gel and the bands were visualized by ethidium bromide staining under U/V light.

For MMP-1 -1607 (1G/2G)

Digestion of the PCR fragments with Xmn I produced 117, 89 and 28 bp for 1G/2G allele, 89 and 28 bp for 1G allele and 117 bp for 2G allele.[15]. (Figure 1).

![Figure 1: Shows a 2% agarose gel picture, stained with ethidium bromide, products digested with Xmn I. M lane: 100 bp - 1kb DNA ladder; lan 1: 1G homozygote (89 bp + 28 bp); lan 2: 2G homozygote (117 bp); lan3: 1G/2G heterozygote (117 bp + 89 bp + 28 bp).](image)

Statistical methods

All statistical analysis was performed using the statistical package for social science (SPSS) version 11 (Chicago, IL, USA). Data were statistically described in terms of mean±standard deviation (±SD), range, or frequencies (number of cases) and percentages when appropriate. Odds ratio (OR) and 95% confidence interval (95%CI) were calculated for all studied polymorphism haplotypes and alleles between cases and controls. P values less than 0.05 were considered statistically significant.

RESULTS

Characteristics of the study participants

This study was carried out on 180 individuals classified into 3 groups: Group I: Control group (n=60): Including 39 (60.6%) males and 21 (39.4%) females with ages ranged from 39 to 61 with a mean value ± SD of 50.32 ± 6.84). Group II: HCV group (n=60): Patients positive for serum HCV Including 36 (60%) males and 24 (40%) females with ages ranged from 43 to 61 with a mean value ± SD of 50.5 ± 5.45). Group III: HCC group (n=60): patients diagnosed with HCC including 34 (56.7%) males and 26 (43.3%) females with ages ranged from 44 to 59 with a mean value ± SD of 52 ± 4.48). TABLE 1 shows the laboratory data of the individuals in the three groups.

Genotype distributions & allelfrequencies of MMP-1 gene polymorphism.

Genotypes.

2G/2G genotype: a higher representation of the 2G/2G genotype was found in HCC group as compared to control group & in HCV group as compared to control group. Statistical significance was observed between Control & HCC(P=0.029 ; OR = 2.25; CI = 1.0838 - 4.6710), a higher representation of the 2G/2G genotype was found in the HCC group when compared to the HCV group (TABLES 2).

1G/2G genotype: 1G/2G genotype was underrepresented when comparing control & HCV group and control & HCC. A Slightly higher representation of the 1G/2G genotype was found between HCV group as compared to HCC group but didn’t reach
Matrix metalloproteinase-1 gene polymorphism is associated with the prognosis

**DISCUSSION**

The study evaluated the effect of -16071G/2G polymorphisms in the promoter region of MMP-1 on the Prognosis of Hepatocellular Carcinoma in Egyptian population.

Many studies have proved that cells containing 2G polymorphism (1G/2G or 2G/2G), which created Ets binding sites, were found to be more transcriptionally active than cells with 1G/1G genotype[14]. Study results showed that 2G/2G individuals have 2.25 times higher
probability of developing HCC when compared to healthy individuals with a statistically significant difference (P=0.0296, CI=1.0838 - 4.6710). These findings are in accordance with Okamoto K et al\[10\] who reported that in MMP-1 genotypes, the 2G homozygotes were significantly more in cirrhotic group than in chronic hepatitis group. Also, B.K. Jang et al\[17\] reported that SNPs of the MMP1 gene contribute to genetic susceptibility to HCC in Korean population. In a recent study MohyEldin et al\[18\] reported that MMP-1 is overexpressed in a large proportion of Egyptian patients with HCC and the high expression level of protein correlated with the disease progression and poor clinical outcome in HCC. Furthermore, MMP-1 high expression proved to be a risk factor for tumor recurrence and independent molecular marker of prognosis in HCC and may become a novel target in the strategies for the prediction of tumor progression and prognosis of this disease. In other carcinomas, Bradbury et al\[19\] reported that 1G/2G and 2G/2G individuals are associated with increased esophageal adenocarcinoma risk (In a Caucasian population, 313 cases & 455 controls). Also Kouhkan et al\[20\] and Woo et al\[21\] reported that 2G/2G individuals are associated with increased Colorectal cancer risk (In an Iranian population, Korean Population - 150,185 cases & 100,304 controls, respectively).

There are also other studies that are not in agreement with our findings, Zhai Y et al\[22\] who reported that there is no association between MMP1 -1607 polymorphism and HCC progression in Chinese patients (434 cases and 480 control). Also, S.Nalbantoglu et al\[11\] reported that although 2G/2G genotype was associated with portal vein invasion (P < 0.02), There was no statistically significant difference in the genotype distributions (P = 0.38) or allele frequencies (P = 0.236) of MMP1 -1607 1G/2G between cases and controls in Turkish population.

There are number of factors which affect Controversial results on polymorphism - disease association studies which also will explain why this study results are not in agreement with previous mentioned studies. Ethnicities of the races: People of different populations have different genetic backgrounds and may be exposed to different environment factors, so the same polymorphism may play different roles in different populations. Also heterogenous nature of cancer diseases and Different MMP regulation mechanisms and microenvironment in different tissues may explain why the same polymorphism plays different roles in different types of cancers.
