ABSTRACT

The present paper represents the systematic solution study of complex formation of Cu (II) ion with Schiff bases synthesized from substituted hydroxybenzaldehyde- \( L_1 = \{4-[(3, 5-diiodo-2-hydroxyphenyl)methylidene]amino\}-1, 5\text{-dimethyl-2-phenyl-1, 2-dihydro-3H-pyrazolone; \ L_2 = \{4-[(2-hydroxyphenyl) methylidene]amino\}-1, 5\text{-dimethyl-2-phenyl-1, 2-dihydro-3H-pyrazol-3-one and \ L_3 = \{4-}\}(5\text{-iodo-2-hydroxy-3-nitrophenyl)methylidene]amino\}-1,5\text{-dimethyl-2-phenyl-1, 2-dihydro-3H-pyrazol-3-one have been studied at 30 \pm 0.1^\circ C and 0.1 M ionic strength in 60\% (v/v) ethanol-water medium. The stability constant of these complexes indicates the formation of 1 : 1 and 1 : 2 complexes with all the Schiff bases.

Key words: Schiff bases, Stability constant, Binary complexes.

INTRODUCTION

Complexation studies are very important from the point of view of analytical and biochemical researches. This study has received the attention of many researchers\(^1\)\(^-\)\(^3\). The extent to which a ligand binds to a metal ion is expressed in terms of stability constants\(^4\)\(^,\)\(^5\). Their determination by potentiometric study at 30 \pm 0.1^\circ C and 0.1M ionic strength in 60\% (v/v) ethanol-water medium has been reported here. The general method for determining the stepwise stability constant for complexes containing simple non-chelating ligands was first described by Bjerrum.

EXPERIMENTAL

All the chemicals, substituted hydroxybenzaldehyde, 4-aminoantipyrine, 2-amino-
pyridine, NaOH, ethanol, transition metal salts, perchloric acid, sodium perchlorate, etc. were of analytical grade. The concentration of metal ions in the solution was determined by standard procedure.

Schiff bases were prepared by condensation reaction of substituted hydroxybenzaldehyde and 2-aminopyridine and 4-aminoantipyrine and characterized by I. R. spectra.

The stability constant of these Schiff bases were determined by Irving and Rossotti technique. The following three sets of the solution were prepared –

(a) 2 mL free HClO$_4$ (0.5M)
(b) Mixt. (a) + 10 mL 0.01M ligand.
(c) Mixt. (b) + 2 mL 0.01M metal ion solution and titrated against 0.2M NaOH solution and total volume of solution was made 50 mL.

RESULTS AND DISCUSSION

Proton ligand stability constant

The acid + ligand curves deviate from acid curve from pH = 8.38 indicating deprotonation of phenolic -OH group in this pH range (Fig. 1).
The values of $\bar{n}_A$ for various pH were calculated and found to be 0.2-0.8 indicating the presence of only one pK for each ligand. pK values calculated by point wise calculations and half integral methods were found to be in good agreement as shown in Table 1. The trends of pK values of Schiff bases are $L_3 > L_2 > L_1$.

**Metal ligand stability constant**

The displacement of metal titration curve along volume axis (Fig. 1) indicates the formation of complex species and lie in pH range, where hydrolysis is not expected. The probability of formation of polynuclear complex was ruled out as the metal concentration was very low.

**Effect of ligand basicity**

The effect of ligand basicity and metal ion on the stability has also been examined. The relation $\log K = a \cdot pK + b$ was tested, since the ligands used in the present work form a close series i.e. they have identical binding sites and hence, the plot of $\log K$ vs. pK is expected to be linear. The validity of the linear relationship has been examined to case of transition metal complexes of substituted ligands by plotting pK vs. $\log \beta$. Since the
difference between log $K_1$ and log $K_2$ is very small, the linear relationship indicates identical binding sites in the ligand.

One would expect that a larger difference between log $K_1$ and log $K_2$ values is due to possible steric hindrance to the linking of second ligand to metal ion and a smaller difference is due to the trans structure. The ratio of log $K_1$/log $K_2$ is small in all cases. Separation factors between the first and second formation constants are well within the expected range and absence of high values implies that there is little or no steric hindrance to addition of second ligand.

**Effect of metal ion**

The stability constant of bivalent metal ion complexes derived from similar type of ligands generally follow the Irving-Williams order. It is clear that the ligands follow the following order of stability in their complexes –

$$L_1 = Cu > Zn > Ni$$

$$L_2 = Zn > Cu > Ni$$

$$L_3 = Cu > Zn > Ni$$

The stability of metal complexes of ligand $L_2$ is similar to the Swami$^{10}$ and ligand $L_1$ and $L_3$ show similar stability of metal complexes to Kalara et al.$^{11}$
